# Pitch Mode Control System Design of Guided Missile 

Muhammad A. R Yass, Mohammed Wajeeh Ameen

#### Abstract

In this paper, the analysis of non-homogenous longitudinal equation of motion for transport Airplane in pitch mode to estimate and calculate the performance of the dynamic motion and Transfer function in pitch mode. The pitch feedback control system diagram with actuator Design to calculate the behavior using time response method for different gain values (K) and Different Gyro sensitivity values (GR) to obtain the best stability, peak value and time response. The results shows that the best stability and control behavior achieved when $K=1.41$ and $G R=1.19$.

Keyword: control system, stability, aerodynamic

## I. INTRODUCTION

Pitch -up is most likely to occur in airplane that have the horizontal stabilizer mounted well above the airplane, common place is the top of the vertical stabilizer[1]. This is sometime done to obtain the end -plate effect on the vertical stabilizer and thus increase effectiveness of the Vertical [2] .Another factor that contributes to this unstable flight condition is the wing a low aspect ratio .such a using has large downwash velocity that increase rapidly as the angle of attack of the wing is increased .as the high horizontal tail moves down into this wake, pitch - up occurs if the downwash velocity becomes high enough. The longitudinal feedback control system was design to hold the airplane in straight and level fight .there is no simple rule to aid.[3]
Engineer in selecting final sensitivity .the final choose usually results in a compromise between the desirability of rapid response and desire to reduce excessive overshot the ability of prediction the systems performance by an analysis that does required the actual solution of The differential equation also we would like to indicate this analysis reading the manner or the method by which this system must be adjusted compensated to produce the desired performance characteristics[4].
Two basic methods available to choose analyze and interpret the state suicidal response of the transfer function of the system obtains an idea of the systems response .this method is based upon the interpretation of SyQuest plot. Although this frequency response approach doesn't yield an exact quantitative prediction of the systems performance i.e. the poles of the control ratio $\mathrm{C}(\mathrm{s}) / \mathrm{r}(\mathrm{s})$ cannot be determine enough information can be obtained to indicate whether the system need to be the system should be compensate [5].

## II. MATHEMATICAL ANALYSIS

The values of the stability derivatives for a four engine jet transport are used. The aircraft is flying in straight and level flight at $40,000 \mathrm{ft}$ with a velocity of 600 ft per sec ( 355 knots), and the compressibility effects will be neglected [6]. The three longitudinal equations were derived in reference to q and as given below: (dynamic notes)

$$
\begin{aligned}
& \frac{m v}{s q} i-\frac{d}{2 U} c m_{\alpha} \alpha+\frac{I y}{s q d} \theta-\frac{d}{2 U} c m q \theta^{\circ}=C F x a \text {. } \\
& \left.-(\mathrm{C} 2 \mathrm{u} \bar{U})+\left[\frac{m u}{s q}-\frac{d}{2 u} C_{2} x\right) \alpha-C_{2 \alpha} \alpha\right] \\
& +\left[\left(\frac{m u}{s q}-\frac{d}{2 u} C_{2} q\right) \theta^{\circ}-\ddot{C}_{w}(\sin (H)) \theta\right]=C F_{2 a} \ldots \ldots \ldots \ldots . \\
& \left(-C_{m o}{ }^{\prime} V+\left(\frac{-d}{2 U} C_{m \alpha}{ }^{\alpha}-C_{m \alpha} \alpha\right)+\left(\frac{I y}{S q d} \ddot{\theta}-\frac{d}{2 U} C_{m q}{ }^{\circ}{ }^{\circ}\right)=c m a \ldots \ldots \ldots . .\right. \text { (3) } \\
& (13.78 \mathrm{~s}+0.088)^{\prime}{ }_{u}(\mathrm{~s})-0.392^{\prime}{ }_{\alpha}(\mathrm{s})+0.7 \theta(\mathrm{~s})= \\
& 0 \text {... ... (4) } \\
& 1.48_{u}^{\prime}(s)-(13.78 s+4.46)_{\alpha}^{\prime}(s)-13.78 s \theta(s)= \\
& 0 \text {....... ... ................... (5) } \\
& 0+(0.0552 \mathrm{~s}+0.619)^{\prime}{ }_{\alpha}(\mathrm{s})+\left(0.514 \mathrm{~s}^{2}+0.192 \mathrm{~s}\right) \theta(\mathrm{s})= \\
& 0 \text {... ... ...... ... ...... (6) }
\end{aligned}
$$

The only nonzero solution of these simultaneous equations requires that the determinate of the coefficient be zero[8]. Thus

$$
\left|\begin{array}{ccc}
13.78 s+0.088 & -0.392 & 0.74 \\
1.48 & 13.78 s+4.46 & -13.78 s \\
0 & 0.0552 s+0.619 & 0.514 s^{2}+0.192 s
\end{array}\right|
$$

Expanding this determinant, the following quartic equation is obtained [7].

$$
\begin{align*}
9754 s^{4}+79 s^{3} & +128.9 s^{2}+0.998 s+0.677 \\
& =0 \ldots \ldots \ldots \ldots(7) \tag{7}
\end{align*}
$$

Dividing through by $\mathbf{9 7 5}$, the equation reduces to

$$
\begin{align*}
s^{4}+0.811 s^{3}+ & 1.32 s^{2}+0.012 s+0.00695 \\
& =0 \ldots \ldots \ldots \ldots \ldots \ldots \ldots(8) \tag{8}
\end{align*}
$$

## Pitch Mode Control System Design of Guided Missile

The transfer function for 6 , input to ' $\alpha$ output in determinant form is

$$
\begin{align*}
& \frac{{ }^{\alpha}(\mathrm{S})}{\delta_{e}}=\frac{\left|\begin{array}{ccc}
13.78 s+0.088 & -0.392 & 0.74 \\
1.48 & -0.246 & -13.78 s \\
0 & -0.710 & 0.514 s^{2}+0.192 s
\end{array}\right|}{\nabla} \\
& \frac{{ }_{\alpha}(S)}{\delta_{e}} \\
& =\frac{-0.01785\left(s^{3}+77.8 s^{2}+0.496 s+0.446\right)}{\left.s^{2}+0.00466 s+0.0053\right)\left(s^{2}+0.806 s+1.311\right)} \tag{9}
\end{align*}
$$

Factoring the numerator

$$
\begin{equation*}
\frac{{ }_{\alpha}(S)}{\delta_{e}}=\frac{-0.01785(s+77.79)\left(s^{2}+0.0063 s+0.0057\right)}{\left.s^{2}+0.00466 s+0.0053\right)\left(s^{2}+0.806 s+1.311\right)} . \tag{10}
\end{equation*}
$$

Going to the alternate form, Eq. [10] becomes

$$
\begin{equation*}
\frac{{ }^{\prime}(S)}{\delta_{e}}=\frac{-1.14\left(\frac{s}{77.79}+1\right)\left[\left(\frac{s}{0.0755}\right)^{2}+\frac{2(0.041)}{0.0755} s+1\right]}{\left[\left(\frac{s}{0.073}\right)^{2}+\frac{2(0.032)}{0.073} s+1\right]\left[\left(\frac{s}{1.14}\right)^{2}+\frac{2(0.352)}{1.145} s+1\right]} . \tag{11}
\end{equation*}
$$

For input to $\theta$ output

$$
\frac{\theta(\mathrm{S})}{\delta_{e}}=\frac{\left|\begin{array}{ccc}
13.78 s+0.088 & -0.392 & 0 \\
1.48 & 13.78 s+4.46 & -0.246 \\
0 & 0.0552 s+0.619 & -0.710
\end{array}\right|}{\nabla}
$$

Expanding and factoring

$$
\begin{equation*}
\frac{\theta(S)}{\delta_{e}}=\frac{-1.31(s+0.016)+(s+0.3)}{\left.s^{2}+0.00466 s+0.0053\right)\left(s^{2}+0.806 s+1.311\right)} \tag{12}
\end{equation*}
$$

Or the alternate form

$$
\begin{equation*}
\frac{\theta(S)}{\delta_{e}(s)}=\frac{-0.95\left(\frac{s}{0.016}+1\right)\left(\frac{s}{0.3}+1\right)}{\left[\left(\frac{s}{0.073}\right)^{2}+\frac{2(0.032)}{0.073} s+1\right]\left[\left(\frac{s}{1.145}\right)^{2}+\frac{2(0.352)}{1.145} s+1\right]} \tag{13}
\end{equation*}
$$

Substituting for $q$ and simplifying, Eq. [10] becomes

$$
\begin{gather*}
\zeta=-\frac{1}{4}\left(\mathrm{C}_{\mathrm{mq}}+\mathrm{C}_{\mathrm{m} \alpha}+\frac{2 \mathrm{I}_{\mathrm{y}}}{\mathrm{Cm}^{2}} \mathrm{C}_{\mathrm{z} \alpha}\right)\left(\frac{\mathrm{cm}^{2}}{\mathrm{I}_{\mathrm{y}}\left(\frac{\mathrm{C}_{\mathrm{mq}} \mathrm{C}_{\mathrm{z} \alpha}}{2}-\frac{2 \mathrm{mC}_{\mathrm{mq}}}{\rho \mathrm{Sc}}\right)}\right)^{1 / 2} .  \tag{14}\\
\quad \frac{{ }_{\alpha}(\mathrm{S})}{\delta_{\mathrm{e}}}=\frac{\left|\begin{array}{cc}
-.246 & -13.78 \mathrm{~s} \\
-0.710 & 0.514 \mathrm{~s}^{2}+0.192 \mathrm{~s}
\end{array}\right|}{\left\lvert\, \begin{array}{cc}
13.78 \mathrm{~s}+4.45 & -13.78 \mathrm{~s} \\
0.0552 \mathrm{~s}+0.619 & 0.514 \mathrm{~s}^{2}+0.192 \mathrm{~s}
\end{array}\right.} . . . . . . . . . .
\end{gather*}
$$

Expanding

$$
\begin{equation*}
\frac{{ }_{\alpha}(\mathrm{S})}{\delta_{\mathrm{e}}(s)}=\frac{-0.01782(s+77.8)}{s^{2}+0.805 s+1.3325} . \tag{16}
\end{equation*}
$$

Going to the alternate form

$$
\begin{equation*}
\frac{{ }_{\alpha}(\mathrm{S})}{\delta_{\mathrm{e}}(s)}=\frac{-1.05\left(\frac{s}{77.8}+1\right)}{\left(\frac{s}{1.15}\right)^{2}+\frac{2(0.35)}{1.15} s+1} . \tag{17}
\end{equation*}
$$

A comparison of Eq. [10] and [12] shows excellent agreement substantiating the original assumption. The $\theta(\mathrm{s}) / \mathrm{\delta e}(\mathrm{~s})$ transferfunction will now be evaluated.

$$
\frac{\theta(S)}{\delta_{e}(s)}=\frac{\left|\begin{array}{cc}
13.78 \mathrm{~s}+4.46 & -0.246  \tag{18}\\
0.0552 \mathrm{~s}+0.619 & -0.710
\end{array}\right|}{\left|\begin{array}{cc}
13.78 s+4.45 & -13.78 \mathrm{~s} \\
0.0552 s+0.619 & 0.514 \mathrm{~s}^{2}+0.192 \mathrm{~s}
\end{array}\right|}
$$

Expanding,

$$
\begin{equation*}
\frac{\theta(S)}{\delta_{e}(s)}=\frac{-1.39(s+0.306)}{s\left(s^{2}+0.805 s+1.3325\right)} \ldots \tag{19}
\end{equation*}
$$

Going to the alternate form

$$
\begin{equation*}
\frac{\theta(S)}{\delta_{e}(s)}=\frac{-0.321\left(\frac{s}{0.306}+1\right)}{s\left[\left(\frac{s}{1.15}\right)^{2}+\frac{2(0.35)}{1.15} s+1\right]} \tag{20}
\end{equation*}
$$

The magnitude plot of Eq. [18] is shown in Figure (2-8).

$$
\frac{\theta(S)}{\delta_{e}(s)}=\frac{13.9 \mathrm{k}(\mathrm{~s}+0.306)}{\mathrm{s}^{5}+10.805 \mathrm{~s}^{4}+(9.375+13.9 \mathrm{GR}) \mathrm{s}^{3}+(13.255+4.253 \mathrm{Gr}+13.9 \mathrm{k}) \mathrm{s}^{2}+4.254 \mathrm{ks}}
$$

$\mathrm{F}(\mathrm{x})=\frac{19.6 x+6}{x^{5}+10.805 x^{4}+25.16 x^{3}+37.196 x^{2}+6 x}$
$\mathrm{F}(\mathrm{x})=\frac{1}{x}+\frac{-0.24071+0.3223 i}{x+1.215-1.62075 i}+\frac{-0.24071-0.3223 i}{x+1.215+1.62075 i}+\frac{-0.0458}{x+8.1967}+\frac{-0.47276}{x+0.178408}$
$\mathrm{Q}=1-\mathrm{d} e^{-z t}-\mathrm{c} e^{-p t}+2 e^{-g t}(-\mathrm{a} \cosh \mathrm{t}+\mathrm{b} \sinh \mathrm{t})$
$\begin{array}{llll}\mathrm{a}=0.24071 & \mathrm{~g}=1.1215 & \mathrm{z}=8.12 & \mathrm{c}=0.4727\end{array}$
$\mathrm{b}=0.3223 \quad \mathrm{~h}=1.6207 \mathrm{p}=0.178 \quad \mathrm{~d}=0.0458$

## III. RESULTS AND DISSECTION

### 3.1. Longitudinal Response at Different K\&GR:

## Table (1):

### 3.2. Discussion

The purpose of this design to obtain largest gain attainable required and the smallest peak overshoot and shortest time setting .From table (3) and figures (8) GR=1.19, maximum K is equal 1.4 and for more than that the system is not stable.
It can be observe from table (1) that by increasing K at constant value of GR, the real part of complex root will decrease and the imaginary part will increase, this mean that the overshoot will increase too and setting time will also increase, so it must have a choose between the largest gain attainable, shortest peak overshoot and shortest time setting. Also by increasing at constant K the real part of complex root will increase and imaginary part will increase too and that increase the peak overshoot and better stability.

So it can't go beyond GR=1.19 and $\mathrm{K}=1.4$ because it is limited by aileron deflection and case study design data which was equal to 5 rad . After compromising all the values of $K$ and GR searching for our design requirement which given above, it found that $\mathrm{GR}=1.19, \mathrm{~K}=1.4$ best selection which must be check it with actuator slewing time (time of actuator to deflect), it can be notice that the maximum value of actuator slewing rate at $\mathrm{GR}=1.19$ and $\mathrm{k}=1.4$ was equal to $43.668 \mathrm{rad} / \mathrm{sec}$ and the design value of actuator slewing rate is equal to $90 \mathrm{rad} / \mathrm{sec}$, that mean the selection value with limit. Also it can be observe that as K increasing the actuator slewing time will also increase and for increasing GR at constant $K$ the actuator slewing time remain same.

## IV. CONCLUSIONS

It can conclude that the response of a control system is examined by root locus method and it depend on real root of the characteristic equation of close loop transfer function and this root depend on $K$ and GR so by increasing $K$ the root shift to right of root locus which decrease the stability but by increasing GR the root shift to the left which increases the stability also increasing K and GR depend on max aileron deflection. The requirement of maximum actuator slewing rate depends on K only because by
increasing GR at constant K the maximum actuator slewing rate will remain the same.
